Prairie Water and Energy Cycling: Budget Assessments, Modeling and Process Diagnostics

Kit Szeto Climate Research Division, Environment Canada

Why Study Water and Energy Cycling?

WATER AND ENERGY CYCLING

Study Foci:
Budget assessments
Modeling
Process diagnostic studies

Budget Assessments Objectives:

- To develop comprehensive baseline climatologies of W +E budgets for the Prairie region by using various quasiindependent datasets
- To assess the relative merits of the various datasets in representing the budgets and to explore implications of the assessment results to the use of these datasets in drought monitoring, model validation and process study applications

Water and Energy Budgets

Atmospheric Water

$$\frac{\partial Q}{\partial t} = E - P + MC + RESQ$$

Surface Water $\frac{\partial W}{\partial t} = P - E - N + RESW$

Atmospheric Temperature

$$C_{p}\frac{\partial\{T\}}{\partial t} = QR + LP + SH + HC + REST$$

Surface Temperature

$$Cv\frac{\partial\{Ts\}}{\partial t} = QRS - LE - SH + G$$

All water storage terms are in mm, T2m in K, enthalpy (H) in 10^9J/km2, moisture fluxes in mm/day energy fluxes in K/day.

Variability among Budgets Assessments - Annual Cycles of Atmospheric Water Budgets

Variability among Budgets Estimatescont.... Surface SH and LE near BERMS Site

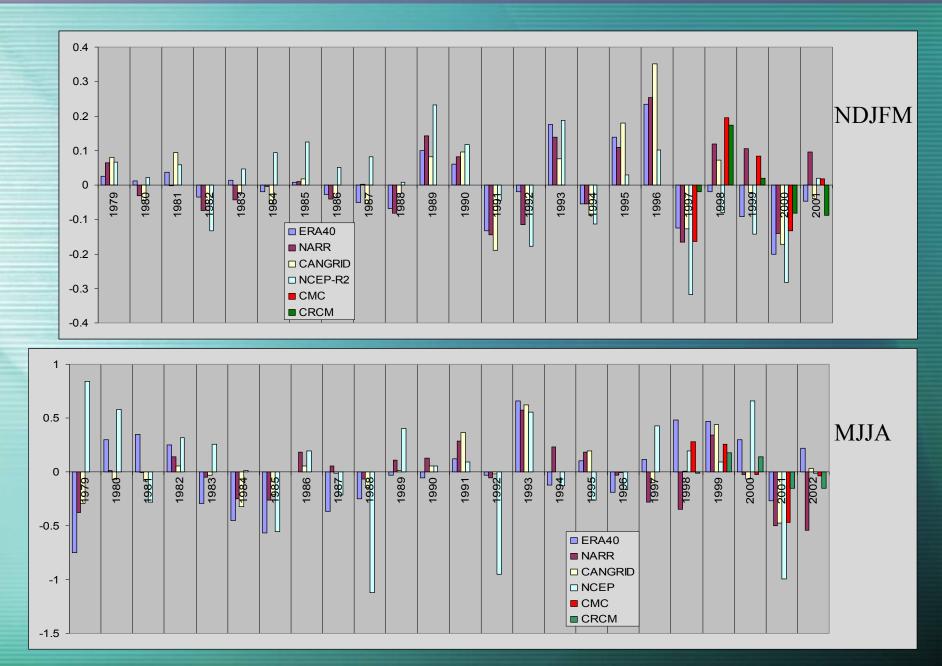

Summary of mean budget results

- Some estimates of budget components compare well to obs but residuals in the balance are often as large as the budget components in all datasets
- Budgets from analysis datasets based on more "modern" assimilation systems (CMC, NARR, ERA-40) compared the best to obs
- * NCEP-R2 over-predicts warm-season water cycling for the region
- * Strong cold bias in CRCM affects its capability to accurately simulate drought in the region
- * Water closure problem (MC >> obs discharge)

Objectives of Study

• To assess the capability and readiness of dynamical predictions of Prairie droughts through a critical evaluation of simulations of the 1999-05 drought with several state-of-the-art RCMs

 To assess the viability of using RCMs as tools for studying Prairie droughts

• To identify major problems that affected the simulations in the different models and to diagnose their causes

Models

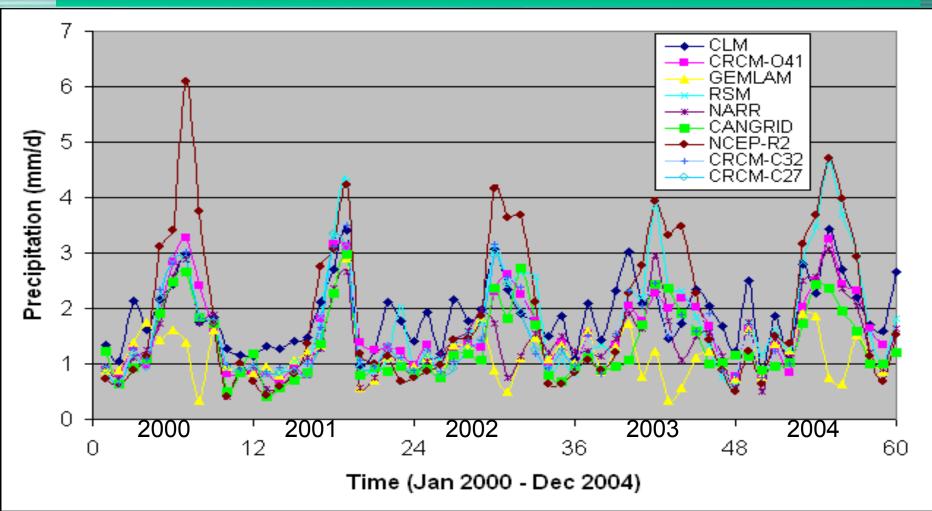

Model	Description	Institute	Notes
CRCM-041	Canadian Regional Climate Model	OURANOS	V. 4.1 – CGCMB, CLASS 2.7, K- F
	66 66 66	EC	CGCM3 - CLASS 2.7, Z-M
	66 66 66	EC	CGCM3 - CLASS 3.2, Z-M
	Global Environmental	EC	
GEMLAM	Multiscale Limited Area Model		RPN, ISBA, K-F, Sunq
CLM	Climate version of the "Lokal Modell"	GKSS (Germany)	TERRA3D, K-F
RSM	Regional Spectral Model	ECPC (US)	GSM, Noah, A-S

Simulations

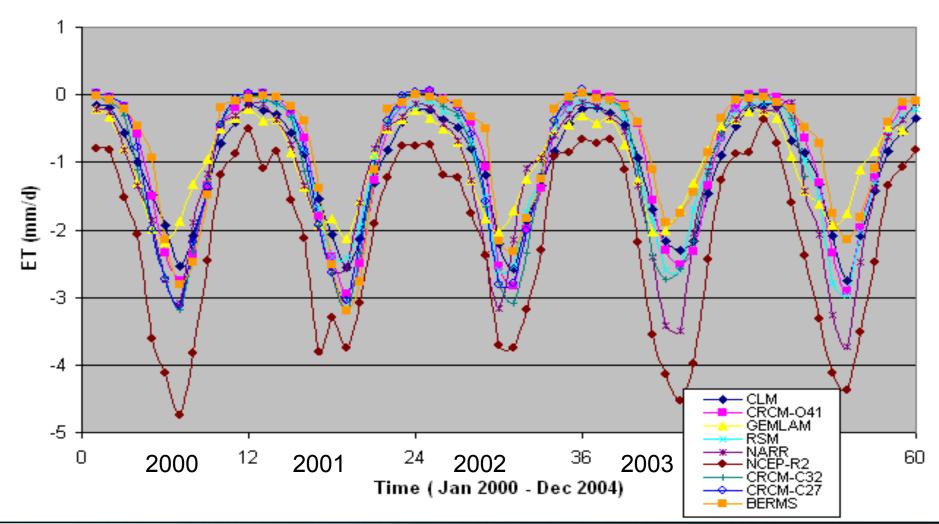

Model domain with elevation

Monthly Timeseries of Areal Mean Precip

- All models captured the low precip of 2000/2001 winter and 2001 summer
- NCEP-R2 and sometimes RSM severely overpredict summer P
- GEMLAM and occasionally NARR severely underpredicts summer precip
- CLM, and to a lesser degree, most models, overpredict winter P (obs could be wrong!)
- CRCM P agrees well with observation, including the general interannual variability of P during the drought
- -dependencies of model bias on large-scale conditions

Monthly Timeseries of ET

- Observed Interannual variability of ET captured quite well by most models
- When compared to BERMS data, most models (except GEMLAM) over-predict ET during the later drought period
- NCEP-R2 severely over-predicts ET
- NARR over-predicts summer ET during 03/04
- GEMLAM under (over)-predicts summer (winter) ET

Summery

- All models captured, to varies degree, the meteorological drought conditions developed during 2000/2001 and the subsequent drying of the surface
- All models also captured the gradual termination of the drought after 2002
- The quality of the predictions are impaired by different deficiencies in the models that need to addressed before improved drought predictions can be expected from the models

Water and Energy Cycling Processes

Main issues of interest:

What intermediate physical mechanisms are involved in determining the hydrometeorological response of the Canadian Prairies to variations in the large-scale circulation

During the winter and
during the summer

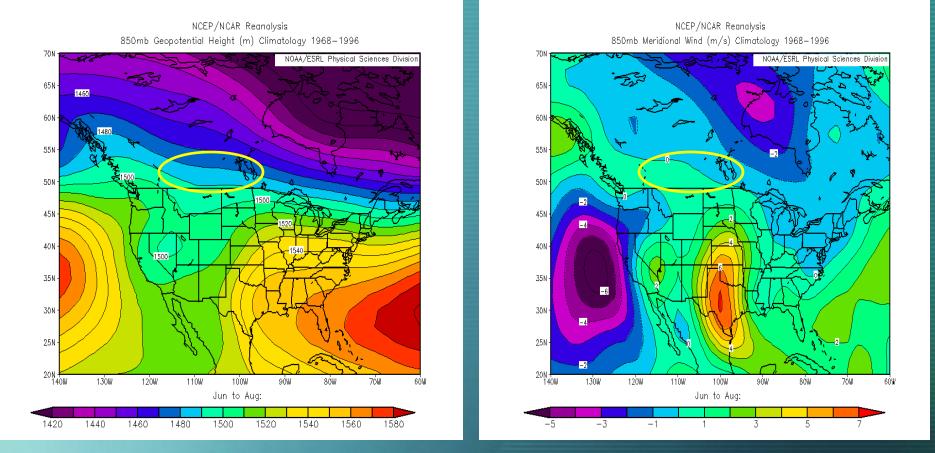

Some discussions related to (1) can be found in: Szeto et al. *BAMS*, 2007, 1411-1425. Szeto, *J. Climate*, 2008, 94-113

	Basin	Mackenzie (JJA)	Mississippi (MJJA)	SRB (JJA)
	Parameter	Р	Р	Р
11111	Е	0.34	0.61	0.21
	Fx	-0.26	-0.10	-0.19
	Fy	0.58	0.44	0.25,0.63*
	ρ	0.17	-0.19	0.00

Correlation coefficients between key JJA ERA-40 water cycle variables and P for Prairies computed over 1979-1999: P (precipitation), E (evaporation), Fx (zonal moisture flux), Fy (meridional moisture flux), ρ (recycling ratio). Correlations exceeding the 95% significance level are highlighted

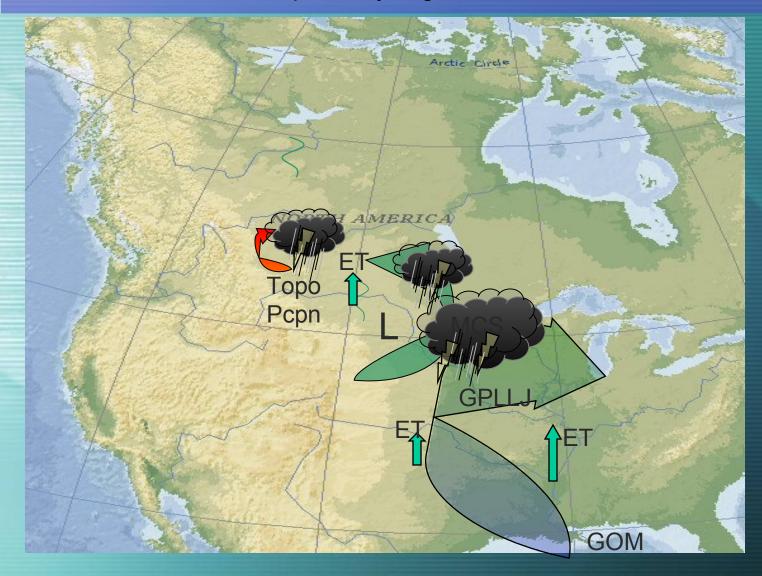

* - correlation between P and seasonal average southerly moisture flux component across 50°N over eastern Prairies

JJA mean circulation at 850 hPa

Mean meridional flow over the prairies is northerly –> mean southerly moisture transports into the Prairies must be accounted for by eddy transports
